ENVIRONMENTAL EFFECTS OF
NORTH SEA OIL AND
GAS DEVELOPMENTS

Edited by
J.P. Hartley and R.B. Clark

Over the past 25 years the North Sea has witnessed a remarkable upsurge in exploration for oil and gas and has now become one of the world’s major hydrocarbon producing areas. Over the same period there has been increasing public and scientific awareness of the damage that can be caused by man’s activities. The North Sea is bordered by heavily industrialized nations and it is no exception to these environmental concerns.

This volume comprises invited papers presented at a two day Discussion Meeting held at the Royal Society, London, on 19 and 20 February 1986 and includes the discussion that followed each paper. The meeting aimed at defining the nature and extent of the environmental effects of 25 years of oil and gas operations in the North Sea. To achieve this, the North Sea was treated as a series of closely coupled systems, each of which was the subject of a paper in which published and unpublished information was reviewed.

This book contains 14 chapters written by invited speakers at the Royal Society Discussion Meeting held in December 1985 on the subject of ribulose bisphosphate carboxylase-oxygenase. This chloroplast enzyme catalyses the key step in the process of photosynthesis, which produces all the food and oxygen required by plants and animals. This step brings into organic form atoms of carbon derived from carbon dioxide present in the atmosphere. The enzyme also catalyses another reaction, the first step in a process called photorespiration, which leads to a loss of carbon atoms as carbon dioxide from the plant. Thus it is the balance between photosynthesis and photorespiration that controls agricultural productivity; this balance is determined by the properties of the enzyme. Ribulose bisphosphate carboxylase-oxygenase is a major target for genetic engineering because if it were possible to alter its properties to favour photosynthesis, major improvements in agricultural productivity could result. The contents of this book discuss all aspects of this important enzyme, from its role in metabolism and properties as a catalyst, to its structure, synthesis, and genetic manipulation.
